17 **Background.** Cannabis use has been reported to be associated with an earlier onset of symptoms in patients with first-  
18 episode psychosis, and a worse outcome in those who continue to take cannabis. In general, studies have concentrated on  
19 symptoms of psychosis rather than mania. In this study, using a longitudinal design in a large naturalistic cohort  
20 of patients with first-episode psychosis, we investigated the relationship between cannabis use, age of presentation to  
21 services, daily functioning, and positive, negative and manic symptoms.

22 **Method.** Clinical data on 502 patients with first-episode psychosis were collected using the MiData audit database from  
23 seven London-based Early Intervention in psychosis teams. Individuals were assessed at two time points – at entry to the  
24 service and after 1 year. On each occasion, the Positive and Negative Syndrome Scale, Young Mania Rating Scale and  
25 Global Assessment of Functioning Scale disability subscale were rated. At both time points, the use of cannabis and  
26 other drugs of abuse in the 6 months preceding each assessment was recorded.

27 **Results.** Level of cannabis use was associated with a younger age at presentation, and manic symptoms and conceptual  
28 disorganization, but not with delusions, hallucinations, negative symptoms or daily functioning. Cannabis users who  
29 reduced or stopped their use following contact with services had the greatest improvement in symptoms at 1 year com-  
30 pared with continued users and non-users. Continued users remained more symptomatic than non-users at follow-up.

31 **Conclusions.** Effective interventions for reducing cannabis use may yield significant health benefits for patients with  
32 first-episode psychosis.

33 *Received 11 December 2012; Revised 15 March 2013; Accepted 19 March 2013*

34 **Key words:** Bipolar affective disorder, cannabis, mania, psychosis, schizophrenia.

## 35 Introduction

36 There is growing evidence that cannabis use may  
37 increase the risk of developing schizophrenia  
38 (Murray *et al.* 2007; Manrique-Garcia *et al.* 2012), and  
39 that individuals with first-episode psychosis with a  
40 history of cannabis use have an earlier onset of psy-  
41 chotic symptoms and younger age at presentation

to services (Gonzalez-Pinto *et al.* 2011; Large *et al.* 42  
2011). Cannabis use has generally been reported to 43  
be associated with increased positive symptoms and 44  
increase in risk of relapse in patients with schizo- 45  
phrenia, with functional and symptomatic improve- 46  
ments reported to occur on discontinuation (Grech 47  
*et al.* 2005; Zammit *et al.* 2008; Foti *et al.* 2010; 48  
Kuepper *et al.* 2011; Faber *et al.* 2012). Cannabis use 49  
has also been shown to affect mood (Henquet *et al.* 50  
2006), being reported to be associated with depress- 51  
ive symptoms and worse outcome in individuals 52  
with bipolar affective disorder (Strakowski *et al.* 53  
2007; van Rossum *et al.* 2009). To our knowledge, 54

(Email: james.m.stone@imperial.ac.uk)

55 no longitudinal studies have yet examined the relation- 108  
 56 ship of cannabis use to symptoms of mania in patients 109  
 57 with first-episode psychosis.

58 In this study, we examined the temporal relationship 110  
 59 of cannabis use to manic and psychotic symptoms and 111  
 60 to age at presentation to services in a large UK-based 112  
 61 cohort of patients with first-episode psychosis. We 113  
 62 hypothesized that cannabis use would be associated 114  
 63 with a younger age of presentation to services, and 115  
 64 that cannabis use would be associated with a greater 116  
 65 level of manic and psychotic symptoms and with 117  
 66 poorer daily functioning. We also hypothesized that 118  
 67 reducing or stopping cannabis use following the first 119  
 68 psychotic episode would be associated with better 120  
 69 symptomatic and functional improvement. 121

## 70 Method 122

71 Ethical approval for this study was obtained from 123  
 72 Wandsworth Research Ethics Committee. The study 124  
 73 was conducted in accordance with the ethical stan- 125  
 74 dards laid down in the Declaration of Helsinki 126  
 75 (1964, 2004). Clinical data were collected using the 127  
 76 MiData audit database from seven London-based 128  
 77 Early Intervention in psychosis teams, covering the 129  
 78 London boroughs of Brent, Camden, City and Hackney, 130  
 79 Islington, Kensington and Chelsea, Lewisham, South- 131  
 80 wark, Wandsworth, and Westminster (Fisher *et al.* 132  
 81 2008; Ghali *et al.* 2012). Within each team, clinicians 133  
 82 (doctors and care-coordinators) completed training 134  
 83 by H.L.F. over a 4.5 h session, including vignettes, 135  
 84 practice sessions, and discussion of standardized rat- 136  
 85 ings, and were required to demonstrate high reliability 137  
 86 with expert raters (Fisher *et al.* 2008). In keeping with 138  
 87 standard practice in the UK for first-episode psychosis 139  
 88 teams, patient inclusion was based on a history of psy- 140  
 89 chotic symptoms that lasted for more than 7 days. Indi- 141  
 90 viduals who only experienced psychotic symptoms 142  
 91 during acute drug intoxication were not included in 143  
 92 the study, but otherwise no prior assumptions were 144  
 93 made about the cause or diagnosis of the psychotic 145  
 94 illness. Individuals were assessed at two time points – 146  
 95 at entry to the service and after 1 year in contact with 147  
 96 the service. On each occasion, the Positive and Nega- 148  
 97 tive Syndrome Scale (PANSS; Kay *et al.* 1987), Young 149  
 98 Mania Rating Scale (YMRS; Young *et al.* 1978) and 150  
 99 the Global Assessment of Functioning Scale disability 151  
 100 subscale (GAF-d; Endicott *et al.* 1976) were rated. At 152  
 101 both time points, the use of cannabis and other drugs 153  
 102 of abuse in the 6 months preceding each assessment 154  
 103 was recorded using the combined Alcohol and Drug 155  
 104 Use scales (Drake *et al.* 1996). Each drug was rated 156  
 105 by clinicians on an operationalized four-point scale 157  
 106 (No use, use, abuse, dependence), as previously 158  
 107 described (Drake *et al.* 1996). On this scale, ‘use’ is 159

defined as substance use with no evidence of persistent 108  
 or recurrent social, occupational, psychological or 109  
 physical problems related to use, and no evidence of 110  
 recurrent dangerous use. ‘Abuse’ is defined as sub- 111  
 stance use with the presence of any of these features. 112  
 ‘Dependence’ is defined as the criteria for ‘abuse’, 113  
 plus at least three of the following seven items: (1) 114  
 much time is spent obtaining or using the substance; 115  
 (2) frequent intoxication or withdrawal interferes 116  
 with other activities; (3) important activities are given 117  
 up because of substance use; (4) continued use despite 118  
 knowledge of substance-related problems; (5) marked 119  
 tolerance; (6) characteristic withdrawal symptoms; 120  
 and (7) the substance is used to relieve or avoid with- 121  
 drawal problems. At the second time point, clinical 122  
 diagnosis and compliance with medication (where 123  
 known) were also recorded. 124

Statistical analyses were completed using R version 125  
 2.14.1 (Ihaka & Gentleman, 1996). We generated a 126  
 linear model with age at presentation to services as 127  
 the dependent variable, and level of cannabis use, 128  
 alcohol use, nicotine use, cocaine use, and stimulant 129  
 use in the preceding 6 months, gender, ethnicity, social 130  
 functioning (GAF-d) and symptoms at presentation 131  
 (PANSS total and YMRS) as independent variables. 132  
 We then generated four separate linear models with 133  
 baseline YMRS, PANSS positive (PANSS-P), PANSS 134  
 negative (PANSS-N) and GAF-d scores as dependent 135  
 variables and level of cannabis use, alcohol use, 136  
 nicotine use, cocaine use, and stimulant use in the pre- 137  
 ceding 6 months, age at presentation, gender and eth- 138  
 nicity as independent variables. In each case, models 139  
 were simplified using an Akaike information criterion- 140  
 based stepwise method implemented in R (Ihaka & 141  
 Gentleman, 1996). Where cannabis was significantly 142  
 related to the dependent variable in each analysis of 143  
 variance (ANOVA), we performed *post hoc* Pearson’s 144  
 correlations on the level of cannabis use *versus* 145  
 the dependent variable, uncorrected for independent 146  
 variables. 147

In the follow-up sample, we compared baseline 148  
 demographics and clinical measures with the full 149  
 (baseline-only) sample using Student’s *t* test and 150  
 $\chi^2$  test, where appropriate. We used four repeated- 151  
 measures ANOVAs to compare YMRS, PANSS (posi- 152  
 tive and negative) and GAF-d ratings at baseline and 153  
 follow-up in three groups based on their change in 154  
 cannabis use over the period of study: (1) patients 155  
 who reported no cannabis use both at presentation 156  
 and 1-year follow-up (‘abstinent’); (2) patients who 157  
 reported a reduction or a discontinuation of their use 158  
 of cannabis (‘reduced’); and (3) patients who reported 159  
 a continuation or increase in their use of cannabis 160  
 (‘continued’). For all analyses, histogram and qq plots 161  
 of residuals were used to confirm normality of data 162

163 and two-tailed  $p$  values were employed to determine  
164 statistical significance.

## 165 Results

166 Baseline data on recent cannabis, cocaine, stimulant  
167 and alcohol use were available in 502 first-episode  
168 patients (320 male, 182 female). Demographic and  
169 clinical details are summarized in Table 1. Age at pres-  
170 entation was predicted by a model driven primarily  
171 by level of cannabis use in the preceding 6 months  
172 (associated with a younger age of presentation;  
173 *post hoc*, uncorrected  $r=0.18$ ,  $n=502$ ,  $p=5 \times 10^{-5}$ ) but  
174 also including level of alcohol use (associated  
175 with an older age at presentation) and ethnicity (see  
176 Table 2). PANSS-P scores were predicted by a model  
177 primarily driven by level of cannabis use (*post hoc*,  
178 uncorrected  $r=0.16$ ,  $n=502$ ,  $p=0.0004$ ), but also includ-  
179 ing nicotine use, age and gender (Table 3). YMRS  
180 scores were predicted by a model that was simplified  
181 to include level of cannabis use only ( $F_{1,500}=16.67$ ,  
182  $r=0.18$ ,  $n=502$ ,  $p=5.2 \times 10^{-5}$ ). PANSS-N scores were  
183 predicted by a model including alcohol use and gender  
184 (Table 4). GAF-d scores were predicted by a model  
185 including nicotine use and gender (Table 5).

186 *Post hoc* analyses of individual PANSS-P and YMRS  
187 components revealed that level of cannabis use was  
188 associated at presentation with increased conceptual  
189 disorganization, excitement and hostility on PANSS-P;  
190 and with elevated mood and increased motor ac-  
191 tivity, sexual interest, irritability, speech (rate and  
192 amount), language (thought disorder), and disruptive-  
193 aggressive behaviour on YMRS (all  $p$  values  $<0.005$ ,  
194  $n=502$ ). Of note, cannabis use at presentation was  
195 not associated with a significantly greater severity of  
196 hallucinations ( $p=0.47$ ) or delusions ( $p=0.25$ ).

197 At the 1-year follow-up, data on cannabis use in 271  
198 first-episode patients were available (54% of baseline  
199 sample). Of these, 143 (53%) were non-users of canna-  
200 bis both at baseline and at follow-up ('abstinent'  
201 group), 80 (30%) were cannabis users at baseline but  
202 had stopped at follow-up ('reduced' group), and 48  
203 (17%) had either continued or increased their level of  
204 cannabis use from baseline to follow-up ('continued'  
205 group). Out of the 271 first-episode patients with  
206 follow-up data, 221 (81%) had a diagnosis of schizo-  
207 phrenia or schizophreniform psychosis, 27 (10%) had  
208 a diagnosis of bipolar affective disorder, 13 (5%) had  
209 a diagnosis of depressive psychosis, and in 10 (4%),  
210 the diagnosis was not recorded. Of those with a final  
211 diagnosis of bipolar affective disorder, nine (34%)  
212 and seven (26%) were classified as being cannabis  
213 abusers and cannabis users, respectively, at baseline.  
214 In terms of medication concordance, 163 (60%) patients  
215 were recorded as being compliant with medication,

19 (7%) as non-compliant, and in 89 (33%) patients, 216  
this information was not available. The sample with 217  
baseline and follow-up data did not differ from the 218  
full (baseline-only) sample in terms of age ( $t=0.91$ , 219  
 $p=0.36$ ), gender ( $\chi^2=1.16$ ,  $p=0.28$ ), ethnicity ( $\chi^2=3.415$ , 220  
 $p=0.64$ ), PANSS-P [mean (s.d.)=19.1 (7.7),  $t=1.55$ , 221  
 $p=0.121$ ], PANSS-N [mean (s.d.)=17.27 (8.6),  $t=1.01$ , 222  
 $p=0.31$ ], YMRS [mean (s.d.)=10.8 (9.6),  $t=0.64$ ,  $p=0.52$ ], 223  
GAF-d [mean (s.d.)=48.9 (17.3),  $t=1.86$ ,  $p=0.62$ ], or 224  
cannabis use ( $\chi^2=1.48$ ,  $p=0.69$ ), at presentation. 225

ANOVA revealed a significant within-subjects effect 226  
of time for PANSS-P ( $F_{1,268}=163$ ,  $n=271$ ,  $p<0.0001$ ), 227  
PANSS-N ( $F_{1,268}=63.6$ ,  $n=271$ ,  $p<0.0001$ ), YMRS 228  
( $F_{1,268}=87.3$ ,  $n=271$ ,  $p<0.0001$ ) and GAF-d ( $F_{1,268}=136$ , 229  
 $n=271$ ,  $p<0.0001$ ), with an improvement in all rating 230  
scales between baseline and follow-up [mean 231  
(s.d.) PANSS-P: 12.2 (6.4), PANSS-N: 12.9 (7.2), 232  
YMRS: 4.7 (6.9), GAF-d: 64.0 (17.6);  $n=271$ ]. There 233  
was a significant interaction between change in 234  
cannabis use ('abstinent', 'reduced', 'continued') and 235  
time for PANSS-P ( $F_{2,268}=9.93$ ,  $n=271$ ,  $p<0.0001$ ; 236  
Fig. 1), YMRS ( $F_{2,268}=9.39$ ,  $n=271$ ,  $p=0.0001$ ; Fig. 2) 237  
and GAF-d ( $F_{2,268}=6.24$ ,  $n=271$ ,  $p=0.002$ ; Fig. 3). 238  
There was no significant interaction between change 239  
in cannabis use and time for PANSS-N ( $F_{2,268}=2.65$ , 240  
 $p=0.07$ ). Compared with individuals in the 'continued' 241  
group for cannabis use, those in the 'abstinent' and 242  
'reduced' groups had lower PANSS-P ( $t=3.26$ , 3.77; 243  
 $p=0.001$ , 0.0003), YMRS ( $t=2.4$  3.57;  $p=0.02$ , 0.0007) 244  
and GAF-d scores ( $t=3.0$ , 3.66;  $p=0.004$ , 0.0004) at 245  
follow-up. Medication concordance was not found to 246  
differ with different patterns of cannabis use (90% 247  
concordance reported in the 'abstinent' group, 90% 248  
in the 'reduced' group and 86% in the 'continued' 249  
group;  $n=102$ , 50, 30, respectively;  $\chi^2=0.32$ ,  $p=0.85$ ). 250

## 251 Discussion

252 In keeping with previous studies, these data suggest 253  
that cannabis use is associated with a younger age of 254  
presentation to services (Gonzalez-Pinto *et al.* 2011; 255  
Large *et al.* 2011), and that discontinuation or reduction 256  
of cannabis use is associated with enhanced symp- 257  
tomatic improvement in patients with first-episode 258  
psychosis (Grech *et al.* 2005; Zammit *et al.* 2008; 259  
Foti *et al.* 2010; Kuepper *et al.* 2011; Faber *et al.* 2012).

260 In contrast, several recent studies of cannabis use in 261  
schizophrenia suggest that change in cannabis use 262  
may not affect symptomatology to such a great extent. 263  
Three studies failed to demonstrate any change in 264  
PANSS-P scores with reduction or discontinuation of 265  
cannabis, although in all of these studies, discontinu- 266  
ation was associated with improvement in social func- 267  
tioning (Gonzalez-Pinto *et al.* 2011; Faber *et al.* 2012; 268  
Barrowclough *et al.* 2013). Another study found that,

EIS, Early Intervention Services; s.d., standard deviation; AC, black African and African-Caribbean; GCSE, General Certificate of Secondary Education; A-level, Advanced-Level General Certificate of Education; HND, Higher National Diploma; PANSS, Positive and Negative Syndrome Scale; YMRS, Young Mania Rating Scale; GAF-d, Global Assessment of Functioning Scale – disability subscale.

although there was no difference in clinical measures between cannabis users and non-users, cannabis users had more frequent hospital admissions (van Dijk *et al.* 2012). A further group reported that individuals who continued to take cannabis were more likely to be compliant with medication, but, after correcting for this, cannabis users had higher levels of psychopathology compared with those who discontinued cannabis (Faridi *et al.* 2012).

Thus, although positive symptoms, as rated by PANSS, are not always associated with cannabis use in patients with schizophrenia and first-episode psychosis, all studies have reported an improvement in functioning with reduction in use. It is also clear that cannabis use may have a complex inter-relationship with medication concordance in some patients, although this did not appear to be an issue in the present study. It is interesting to note that, although we found that cannabis did have an effect on PANSS-P scores in the present study, this effect was primarily driven by aggression and disinhibition, rather than the more usually associated symptoms of delusions and hallucinations.

It is possible that the effects of cannabis reduction on illness outcome may be most marked in patients with first-episode psychosis. A recent meta-analysis found that reducing substance intake led to improvements in symptomatology, but that this effect was only present in patients with first-episode psychosis. In patients with more established illness, improvements were not statistically significant (Mullin *et al.* 2012).

Although other studies have found that cannabis use is associated with increases in positive affect (self-rated reports of happiness, cheerfulness, relaxation, enthusiasm and satisfaction) in the general population (Henquet *et al.* 2006), and that it can worsen outcome

**Table 2.** Components of general linear model predicting age at presentation<sup>a</sup>

	Estimate (S.E.)	<i>t</i>	<i>P</i>
Intercept	25.5 (3.33)	7.66	$9.5 \times 10^{-14}$

<sup>a</sup>  $F_{3,498} = 5.76$  ( $p = 0.0002$ ).

305 in bipolar disorder (Strakowski *et al.* 2007; van Rossum  
 306 *et al.* 2009), our study is the first report, to our knowl-  
 307 edge, of cannabis use being associated more closely  
 308 with manic-type symptoms than with hallucinations  
 309 and delusions in patients with first-episode psychosis.  
 310 Our finding of an association between cannabis  
 311 use and a younger age of presentation to services is  
 312 in keeping with current evidence that cannabis use  
 313 may lead to an earlier onset of psychotic symptoms  
 314 (Large *et al.* 2011). It is possible that individuals  
 315 with earlier and more severe symptoms may be  
 316 drawn to take cannabis for other reasons, or that  
 317 younger individuals may simply be more likely to  
 318 have taken cannabis in the preceding 6 months due  
 319 to cannabis use being more prevalent in a younger  
 320 age group. However, a recent meta-analysis concluded  
 321 that these possibilities could not fully explain the  
 322 association between cannabis use and earlier onset of  
 323 psychosis (Large *et al.* 2011). It should be noted that  
 324 the 6 months prior to contact with services may have  
 325 coincided with the onset of prodromal symptoms,

**Table 4.** Components of general linear model predicting PANSS negative scores at presentation<sup>a</sup>

	Estimate (S.E.)	<i>t</i>	<i>P</i>
Intercept	16.62 (0.70)	23.75	$2 \times 10^{-16}$
Alcohol use	-1.30 (0.56)	-2.48	0.013
Gender, male	1.55 (0.77)	2.02	0.044

PANSS, Positive and Negative Syndrome Scale; S.E., standard error.

<sup>a</sup>  $F_{2,499} = 4.634$  ( $p = 0.01$ ).

**Table 5.** Components of general linear model predicting GAF-d scores at presentation<sup>a</sup>

	Estimate (S.E.)	<i>t</i>	<i>p</i>
Intercept	54.2 (1.37)	39.69	$2 \times 10^{-16}$
Nicotine use	-1.74 (0.87)	-2.00	0.046
Gender, male	-2.74 (1.65)	-1.66	0.097

GAF-d, Global Assessment of Functioning Scale – disability subscale; S.E., standard error.

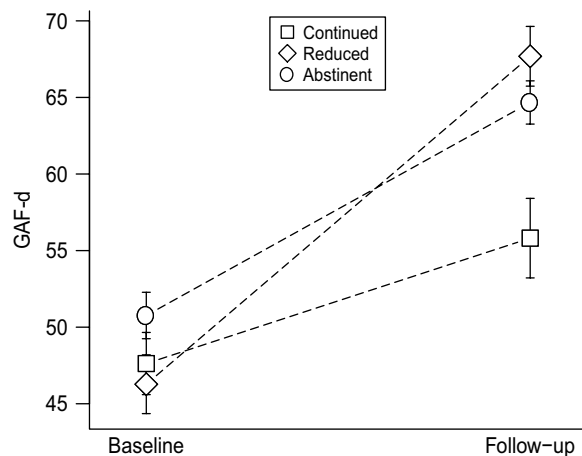

<sup>a</sup>  $F_{2,499} = 3.954$  ( $p = 0.01$ ).

**Fig. 1.** Interaction plot of the positive subscale of the Positive and Negative Syndrome Scale (PANSS-P) over time. The figure shows PANSS-P scores in patients with first-episode psychosis who reported no cannabis use both at presentation and 1-year follow-up ('abstinent'), who reported a reduction or a discontinuation of their use of cannabis ('reduced'), and who reported a continuation or increase in their use of cannabis between baseline and follow-up ('continued'). Values are means, with standard errors represented by vertical bars.

**Fig. 2.** Interaction plot of the Young Mania Rating Scale (YMRS) over time. The figure shows YMRS scores in patients with first-episode psychosis who reported no cannabis use both at presentation and 1-year follow-up ('abstinent'), who reported a reduction or a discontinuation of their use of cannabis ('reduced'), and who reported a continuation or increase in their use of cannabis between baseline and follow-up ('continued'). Values are means, with standard errors represented by vertical bars.

**Fig. 3.** Interaction plot of the Global Assessment of Functioning scale - disability subscale (GAF-d) over time. The figure shows GAF-d scores in patients with first-episode psychosis who reported no cannabis use both at presentation and 1-year follow-up ('abstinent'), who reported a reduction or a discontinuation of their use of cannabis ('reduced'), and who reported a continuation or increase in their use of cannabis between baseline and follow-up ('continued'). Values are means, with standard errors represented by vertical bars.

326 and we cannot exclude the possibility that cannabis  
327 was used in an attempt to self-medicate.

328 It is interesting to note that, in the present study, the  
329 level of PANSS-P scores at baseline was associated  
330 with nicotine use (at trend level) and with age, and  
331 that lower GAF-d scores at baseline were also associ-  
332 ated with nicotine use. Previous studies have reported  
333 an association between nicotine use and a greater  
334 severity of positive symptoms, as well as lower social  
335 functioning, in patients with first-episode psychosis  
336 and schizophrenia (Krishnadas *et al.* 2012; Zhang  
337 *et al.* 2012). Although the reasons for these associations  
338 have not been ascertained, it is possible that nicotine  
339 use may worsen symptoms and levels of disability,  
340 or may be used as self-medication in an effort  
341 to improve some aspects of functioning in the most  
342 unwell patients (Krishnadas *et al.* 2012; Zhang *et al.*  
343 2012). The reason for our finding of an association  
344 between age and symptoms in this study is not  
345 known, but it is possible to speculate that older indi-  
346 viduals were more likely to have been living away  
347 from home, with less daily contact from family mem-  
348 bers, and so their illness may have become more severe  
349 before being recognized.

350 We also found an association between alcohol use  
351 and less severe negative symptoms and between  
352 male gender and more severe negative symptoms.  
353 The finding of an association (albeit weak) between  
354 alcohol use and less severe PANSS-N scores has not

355 been previously reported, to our knowledge, and  
356 may simply reflect the fact that individuals with  
357 lower negative symptoms are more capable of getting  
358 access to alcohol. The finding that male gender was  
359 associated with PANSS-N scores has been established  
360 for many years (Andreasen, 1982; Abel *et al.* 2010).

361 There are limitations to this study, most notably that  
362 cannabis and other drug use data were dependent on  
363 patient recall and disclosure - the alcohol and drug  
364 use scales are self-report scales. Furthermore, the data  
365 were recorded by a variety of different psychiatric  
366 team members who were not blind to treatment  
367 status, though all had received the same training.  
368 Only 27 patients were diagnosed with bipolar affective  
369 disorder at follow-up; therefore, manic-type symp-  
370 toms, although associated with cannabis use, were  
371 unlikely to have been the primary presenting com-  
372 plaint in the majority of cases. Data on cannabis use  
373 at follow-up were not available in approximately 46%  
374 of the original sample. This was because follow-up  
375 assessments were abbreviated in some instances, with  
376 recordings of substance use being omitted, due to  
377 time pressures on the clinical teams involved in the  
378 study. Although the baseline demographics and clinical  
379 measures in patients with substance use data at  
380 both time points did not differ significantly from  
381 those with data from the first time point only, it is  
382 possible that the longitudinal analysis may not be  
383 fully representative of the total study population.

384 Despite these limitations, the findings from this  
 385 study are derived from a relatively large naturalistic  
 386 cohort with a good coverage of different London  
 387 teams and regions and so should be generalizable to  
 388 other inner-city services in the UK. This study suggests  
 389 that efforts to identify effective interventions for redu-  
 390 cing cannabis use are likely to yield significant health  
 391 benefits for patients with first-episode psychosis.

#### 392 Acknowledgements

393 Initial pilot work within Camden and Islington  
 394 Early Intervention Services (EIS) was supported by  
 395 Islington Primary Care Trust (PCT). We are extremely  
 396 grateful to clinicians and patients from the teams  
 397 participating as part of the MiData Consortium for  
 398 their time and enthusiasm: Camden and Islington  
 399 EIS, EQUIP Team (Hackney EIS), Lewisham EIS,  
 400 Southwark Team for Early Psychosis (STEP),  
 401 Wandsworth EIS, Westminster and Kensington &  
 402 Chelsea EIS, and Brent EIS. There were no funding  
 403 sources.

#### 404 Declaration of Interest

405 A.H.Y. has received research grants, honoraria for  
 406 educational activities and fees for consultancy ser-  
 407 vices from a number of pharmaceutical companies  
 408 (AstraZeneca, BCI Pharma, Bristol-Myers Squibb,  
 409 Eli Lilly, GlaxoSmithKline, Janssen, Novartis, Otsuka  
 410 Pharmaceutical Co., Pfizer, Sanofi-Aventis, Servier  
 411 Laboratories and Wyeth). J.M.S. has received a non-  
 412 restricted academic fellowship from GlaxoSmithKline,  
 413 and honoraria from Roche, AstraZeneca, Behrenberg  
 414 Bank and Pfizer.
